FÖREWORD

This paper was prepared as a result of a suggestion made by Mr. Warren Grabau of the Army Engineers Waterways Experiment Station in Vicksburg, Miss. It was subsequently requested by Dr. Clark Crain, Project Leader of Project DUTY of the Advanced Research Projects Agency. This paper constitutes a part of the results of RAC Study IR-208.

Problem

To present by means of coding tables an improved and expanded system of organizing information descriptive of factors bearing on military operations for use in research.

Facts

Several environmental coding handbooks and lists of environmental factors pertinent to military activities have been prepared in the past.

Cross correlations between environmental and/or operational factors and the effects they induce have been limited in effectiveness because the lists of factors considered have been inadequate. In the interests of keeping the study simple, reducing the number of measurements or observations, or because appropriate scales of measurement did not exist, the tendency has been to give most attention to the simple environment-and-response relation and comparatively little to more complex relations such as that of the mission-environment-organization-tactics-response combination.

Discussion

There is a need for a system that would permit researchers in the military field to compare and correlate such widely variant factors as combat organization, material performance, environmental condition, and success of mission. It seemed desirable so to organize these data that a correlation between characteristics of military operational experience and of operational environments could be explored.

A coding handbook that combines the coding systems used in descriptions of materiel performance, historical records of military operations, and descriptions of environmental conditions has been formulated. To explore the military meanings of the characteristics of places it seems essential to begin with the formulation of just such a complex matrix as is presented here. A conceptual skeleton of this kind is needed as an aid to the organization of a wide range of historical experiences and experimental results. It is needed as an aid or tool in the exploration of military-environmental relations and the testing of conceptual models for prediction.

This coding handbook is presented as an aid in the identification and correlation of elements and factors that are of importance in the study of military environments and military operations; it shows how they can be numerically identified. The characteristics of the storage and retrieval system or systems that might be used in the employment of this system are outside the scope of this paper.

It is anticipated that this system will facilitate area analysis and contribute to increased speed and effectiveness of military planning. It should also contribute to the study of optimum standards or criteria for the design of materiel; the structuring of military organizations, tactical systems, or operating procedures; and the formulation of training programs for the various military theaters of operation. The system presented here is a tool for research in the fields of computer simulation of battle and simulation of logistical support, for the establishment of requirements for types of organization and equipment, and for the evaluation of military capability under specific circumstances.

A Coding System for Describing Factors Related to Military Operations

INTRODUCTION

NEED

The coding system presented in this paper was prepared in recognition of several very different needs. It would be presumptuous to try to delineate all possible future uses for a scheme for organizing and comparing a complex body of information. However, experience with this and similar codes has demonstrated potential usefulness in such areas as are presented below.

The general problem of military science, of which this problem is but a part, may be stated: "What is the precise nature of military activities, expressed in quantitative and interrelated terms?" A related problem is: "What is the magnitude of the effect of environmental conditions at a specific place on a specific military activity?" Research related to this latter problem has many uses for lists or coding systems of the kind presented in this paper. They have been or could be used in:

- (a) establishment of a research and development (R&D) program through the identification of requirements for new capabilities or properties of materiel;
- (b) formulation of a program of test and evaluation through the identification of places and times at which desirable test conditions existed;
- (c) establishment and improvement of a program for intelligence collection through the development of new uses of data and new, expanded, or improved methods of data collation and interpretation;
- (d) establishment and improvement of supply systems through increased consideration of special conditions and unusual consumption rates in the specific areas to be supplied;
- (e) development of improved tactical doctrine and improved aids and systems for training through an increased consideration of specific conditions in areas of potential military importance;
- (f) the development of improved systems for the evaluation of readiness, efficiency, strength, capability, and requirements through improved understanding of the complex relations between organization type and size, training, equipment, mission, tactics, and environmental conditions.

The list and coding key presented below represent an attempt to combine and add to the advantages of previous lists and to handle both past and potential events in a single system. It is formulated on the assumption that the most efficient data code is the one that is most flexible and serves the greatest number of users. It is intended that this handbook should be used to describe activities of all services, all missions, all places, and all times. It is not

necessary for complete data to be at hand, but it is intended that there be a place for available information.

This key is designed to permit the ready inclusion of data from earlier studies and of supporting and more detailed information concerning organization, mission, tactics, operations, and environments. No particular processing procedure is intended or implied.

EVOLUTION

Various coding keys for the organization of data—or the storage and retrieval of data—concerning the relation between environmental conditions and military activities have been prepared in the past. It seems appropriate to mention the following six:

Sherman List. This comprehensive list of environmental factors of military importance (part of which is reproduced in ORO-R-41) was prepared about 1949 and was used in the development of a program of research in environmental protection in the Office of the Quartermaster General.

Clark University List.² This list, also very comprehensive, was compiled by the School of Geography, Clark University, in 1952-54. It pointed out the wide variance in definitions of environment and the variance associated with changes in the scale of the problem.

ACE Committee List.³ This list originated in the Panel on Environmental Research of the Army Committee on Environment in 1960. Unlike the others it sought to reduce the list of factors to those it had reason to believe were of greatest importance, and was essentially limited to measurable atmospheric and terrain factors. The list was approved and circulated by CONARC as guidance in the development of environmental test programs.

Envanal List.⁴ This list was inherent in the Envanal (Environmental Analysis of Military Items and Equipment) System proposed in 1954 by Dunlap and Associates. Although the system allowed for terrain factors, emphasis was placed on climatic factors and on the relation between climate and performance. Records of environmental tests of ordnance equipment in the Envanal format are still being kept by the Southwest Research Institute acting under contract with the Ordnance Corps and more recently by the Army Materiel Command.

George Washington University List.⁵ This list, used by the George Washington University School of Engineering in its 1956 study of the effects of environment on military activities as indicated in the historical records of WWII and Korea, is very different. For the first time the descriptive elements of organization, activity mission, environmental element, material, personnel, and effects were combined into a single system that permitted comparison and correlation. This study demonstrated that it was feasible in concept to explore the military meaning of environmental conditions by comparing them with military experience under those conditions.

University of South Carolina List.⁶ This list, prepared in 1959 by the Geology Department of the University of South Carolina, is essentially an expansion of the George Washington University list. This contract report is interpreted as verifying the conceptual feasibility of testing the military

relevance of environmental conditions by the use of published data. This study gave greater attention to doctrine and test results than the George Washington University list, which emphasized after-action reports.

Coding systems and environmental-factors lists have tended to be limited in scope and primarily intended to serve the interests and objectives of either intelligence, R&D, testing, or planning. However, the evolution of these lists and systems is interpreted to indicate a trend toward consideration of the effects of groups of environmental factors that coexist in time and place and toward the prediction of performance from the analysis of environments.

It is appropriate to allow for the extension of these trends and also for the introduction and simultaneous consideration of data that come from a variety of different sources but increase the understanding of the conditions and activities at a particular place at a particular time. Thus for example an after-action report might be augmented by a report of test results on equipment used, intelligence reports, weather records, and separately derived terrain measurements in an effort to derive the fullest understanding of the event.

A reader who compares the tables in the Coding Handbook of the Historical Records Project of the George Washington University (1954)¹ and the Coding Handbook of the Historical Records study of the University of South Carolina (1959)² with the tables presented here will notice an essentially consistent trend toward quantitative expression, increased precision, added detail, and greater breadth of interest. By such comparison it may be found that scales for the expression of four additional considerations have been introduced: (a) comparison of opposing forces; (b) description of tactics and the geometry of battle-fields; (c) description of civil affairs and the social, economic, and political environment; and (d) more detailed and quantitative description of other environmental conditions. The scope and flexibility of the tables have been increased by removing the limitations on the time span in the data code, allowing for records of obsolete equipment and for a separation of missions and functions from any particular organizational structure.

Insofar as seemed feasible, preexisting scales, tables, and descriptive methods were used. The vegetation codes are expressed by six height categories or strata of plant associations and are further expressed in terms of diameter of stems at breast height, continuity of crowns, and characteristics of foliage in accord with already established methods for the description of the structure of plant associations. The soil code is expressed in terms of the Army unified soils classification system. The economic structure is encoded in terms used by the US Bureau of the Census. The weather elements are essentially expressions of the international weather code as used by the US Weather Bureau.

A different basis for the coding of materiel is used. Earlier codes have been based on the Federal supply classification. In the interests of simplicity and freedom to include obsolete items of equipment or items that may be invented in the future, a different classification is used. It is derived from the standard industrial code⁸ and organized in terms of military function. Increased flexibility in the designation of materiel is also gained by increasing the space allowed for the item name over that allowed in the Envanal system.⁴ In this way military elephants might be included even if they did not appear in the Federal Supply Catalogue.

In a few of the tables, such as those related to tactics and operational performance and effects, it seemed desirable to invent scales of description. However, most of the other tables are drawn from previously existing scales and were modified in the interests of increased detail, increased flexibility, or increased applicability. Preference was given to expression in terms of actual reported measurements or numbers.

CODING SYSTEM STRUCTURE

The coding system presented below consists of 10 parts:

- 1. <u>Identifiers</u>, including the general kind of environment and geographical location and date of the incident. It is designed to permit the mechanical retrieval of data by region or coordinate system as well as by subject and period.
- 2. Descriptors, including nationality, organization, unit size, unit composition, mission, and tactics of both opposing forces.
- 3. Operational elements, including environmental elements, functions and functional systems, and tactical applications and results (Tables 17-24).
- 4. Personnel and materiel, including identification, action status, and performance characteristics.
- 5. Atmospheric environment, including visibility, temperature, humidity, wind, snow, clouds, and weather type.
- 6. Geologic environment, including elevation, relief, texture, microrelief, slope, soil, and state of the ground.
- 7. <u>Hydrographic environment</u>, including depth, surf, current, temperature, ice, and bottom conditions.
 - 8. Biological environment, including vegetation and animals.
- 9. Cultural environment, including population density, literacy, labor force, employment, religion, language, social agglomeration, political structure, government, and transportation.
- 10. Geometry, including line of combat, geometry of the battle zone, and range of action.

The application of this coding system is illustrated by a sample work sheet presented in Fig. 1. It represents the organization of information derived from published sources. The relation between raw data and encoded information is shown in Sample Table 1. Here a single event, the first presented in Fig. 1, is illustrated in greater detail. This event describes action near Aitape on New Guinea in 1944. Pertinent information is quoted from a published source; the code data are presented and the interpretation of the coded data is given. Inputs can be compared with retrieved information. For the purposes of this illustration, data from several sources have been included.

Sample Table 1 illustrates the limitations of encoded data, for in the interests of achieving comparability between events a standard list of descriptive terms is used. This results in a certain loss of detail and of accuracy and specificity of description.

The coding keys have developed empirically in response to various needs over a period of at least two decades. They are the products of evolutionary

growth influenced by successive redefinitions of terms, by improved means of measuring environments and military effects, and by increased understanding of the interaction between environments and military affairs. In order to facilitate the use of already-coded data, the previous coding systems were altered as little as possible in the development of this code.

In terms of simplicity and ease of handling data it is unfortunate that the environmental analysis of military affairs does not fit into a smaller and more compact framework. However, neither military activities nor the environments in which they are conducted are simple matters. Even though this key is 2 or 3 times larger than its predecessors, it is likely also to prove to be too abbreviated. All possible questions cannot be anticipated; no one can foresee all future needs. Therefore an allowance has been made in the construction of these tables for the addition of at least a moderate amount of new or other factors. On the other hand if the military meaning of environments and the military evaluation of geographic places are to be contemplated, some matrix such as is here described must be involved.

None	Source of information a	Smith, Robert R., "The Approach to the Philippines" b, 10

^aFor purposes of this illustration, information from several sources has been included.

[Battle of the Driniumor (Aitape) 10 July to 11 August 1944¹⁰]

The situation in the 2d Platoon's sector was quite different [July 13]. There the ground was covered with Sago palms, underbrush, and heavy jungle growth which limited visibility to five or ten yards. The platoon ran into concentrated rifle and machine gun fire immediately after starting its attack and was unable to force a crossing of the small stream Because the dense rain forest masked their fires, mortars and heavy machine guns could not support further advances in the inland sector. [pp 118-119]

Radio communications presented no particular problems in the coastal region, but inland radio trouble was chronic and sometimes acute. Radio range was limited, especially at night, by dense jungle and atmospheric conditions, while almost daily tropical storms originating over the Torricelli Mountains hampered both transmission and reception. At times the only way radio could be employed in the Afua area was by having artillery liaison sets transmit to artillery liaison planes flying directly overhead. [p 128]

The 2d Squadron [10 July] did not follow any trail but . . . cut its way through heavy jungle over alternately hilly and swampy terrain. The nature of the terrain slowed progress so much that . . . [in 4% hours] the squadron . . . [had not advanced] more than a mile. . . . [p 139]

Terrain difficulties, aggravated by the rain, forestalled progress that night [11-12 July], and at 1845 Col. Bloch's group bivouacked for the night . . . only one and a half miles west of the starting point [which they left at 1530]. [p 157] ... the 3d Battalion ... was held up by a Japanese force of platoon strength. In the dense jungle it was almost an hour before the Japanese could be dispersed and the advance continued. [p 163]

Patrolling thoroughly in heavily jungled terrain, the battalion [1st Bn, 127th Inf.] bivouacked for the night of 18-19

July some 400 yards west of its objective. [p 169]

Actually, neither the Japanese nor South Force had any accurate knowledge of each other's strengths and dispositions in the Afua area. Each side complained that the other held isolated strong points, none of which appeared to be key positions. Both sides employed inaccurate maps, and both had a great deal of difficulty obtaining effective reconnaissance. In the jungled, broken terrain, near Afua, operations frequently took a vague form-a sort of shadow boxing in which physical contact of the opposing sides was ofttimes accidental. [p 182]

The unit [Burns' battalion] encountered no opposition but found itself in such a maze of steep ridges and deep gullies that the pace of advance was slowed to little more than 100 yards per hour. After marching over ten hours and

covering over 1,000 yards . . . [p 195]

Radio communication between battalions, from battalions to TED Force headquarters, and from the latter to higher echelons was nearly nonexistent, for the heavy jungle and the damp weather cut down the efficiency of all radio equipment. [pp 194-195]

bMajor source of information encoded in Sample Table 1.
